## Lecture 6

### Regularization - Algorithms for Ridge and Lasso

# Announcements

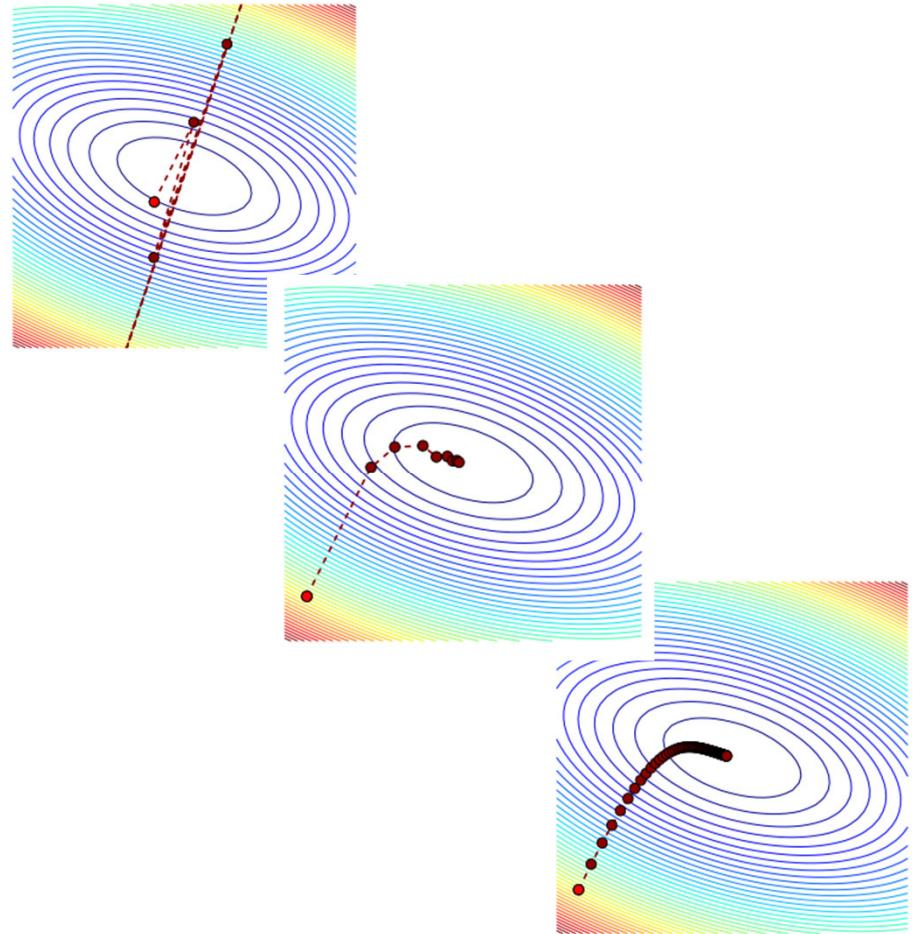

- ▶ Homework 3 extended to Sunday October 27 at 11:59pm
  - ▶ Midterm in class on Wednesday October 23 1-2:40pm.
    - ▶ Exam will be pencil and paper with cheat-sheets
    - ▶ Section 7 will review relevant material
    - ▶ Practice exam will be posted on Thursday October 17.
  - ▶ Project 1 Proposal due Sunday November 3.
    - ▶ We will discuss sample projects in Section 8.
    - ▶ Please post to the Forum about the project.

# Review

- ▶ Fixed Step Size
  - ▶ Learning rate  $1/(\max \text{ of derivative})$
  - ▶ Number Iterations  $O(1/\text{error})$
- ▶ Varying Step Size
  - ▶ Back-tracking Line Search
    - ▶ Number Iterations  $O(1/\text{error})$  with better constant
  - ▶ Strongly Convex Functions
    - ▶ Learning rate  $1/(\text{iteration})$
    - ▶ Number Iterations  $O(\log(1/\text{error}))$

## Bound on Derivative

**Definition** (Lipschitz continuity). A function  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  is Lipschitz continuous with Lipschitz constant  $L$  if for any  $\vec{x}, \vec{y} \in \mathbb{R}^n$

$$\|f(\vec{y}) - f(\vec{x})\|_2 \leq L \|\vec{y} - \vec{x}\|_2.$$

# Bound on Derivative

**Definition** (Lipschitz continuity). A function  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  is Lipschitz continuous with Lipschitz constant  $L$  if for any  $\vec{x}, \vec{y} \in \mathbb{R}^n$

$$\|f(\vec{y}) - f(\vec{x})\|_2 \leq L \|\vec{y} - \vec{x}\|_2.$$

**Theorem** If the gradient of a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  is Lipschitz continuous with Lipschitz constant  $L$ ,

$$\|\nabla f(\vec{y}) - \nabla f(\vec{x})\|_2 \leq L \|\vec{y} - \vec{x}\|_2$$

then for any  $\vec{x}, \vec{y} \in \mathbb{R}^n$

$$f(\vec{y}) \leq f(\vec{x}) + \nabla f(\vec{x})^T (\vec{y} - \vec{x}) + \frac{L}{2} \|\vec{y} - \vec{x}\|_2^2.$$

# Gradient Descent Decreases Function

**Corollary** . Let  $\vec{x}^{(i)}$  be the  $i$ th iteration of gradient descent and  $\alpha_i \geq 0$  the  $i$ th step size, if  $\nabla f$  is  $L$ -Lipschitz continuous,

$$f(\vec{x}^{(k+1)}) \leq f(\vec{x}^{(k)}) - \alpha_k \left(1 - \frac{\alpha_k L}{2}\right) \|\nabla f(\vec{x}^{(k)})\|_2^2.$$

# Gradient Descent Decreases Function

**Corollary** Let  $\vec{x}^{(i)}$  be the  $i$ th iteration of gradient descent and  $\alpha_i \geq 0$  the  $i$ th step size, if  $\nabla f$  is  $L$ -Lipschitz continuous,

$$f(\vec{x}^{(k+1)}) \leq f(\vec{x}^{(k)}) - \alpha_k \left(1 - \frac{\alpha_k L}{2}\right) \|\nabla f(\vec{x}^{(k)})\|_2^2.$$

*Proof.* Applying the quadratic upper bound we obtain

$$f(\vec{x}^{(k+1)}) \leq f(\vec{x}^{(k)}) + \nabla f(\vec{x}^{(k)})^T (\vec{x}^{(k+1)} - \vec{x}^{(k)}) + \frac{L}{2} \|\vec{x}^{(k+1)} - \vec{x}^{(k)}\|_2^2.$$

# Gradient Descent Decreases Function

**Corollary**     Let  $\vec{x}^{(i)}$  be the  $i$ th iteration of gradient descent and  $\alpha_i \geq 0$  the  $i$ th step size, if  $\nabla f$  is  $L$ -Lipschitz continuous,

$$f(\vec{x}^{(k+1)}) \leq f(\vec{x}^{(k)}) - \alpha_k \left(1 - \frac{\alpha_k L}{2}\right) \|\nabla f(\vec{x}^{(k)})\|_2^2.$$

*Proof.* Applying the quadratic upper bound we obtain

$$f(\vec{x}^{(k+1)}) \leq f(\vec{x}^{(k)}) + \nabla f(\vec{x}^{(k)})^T (\vec{x}^{(k+1)} - \vec{x}^{(k)}) + \frac{L}{2} \|\vec{x}^{(k+1)} - \vec{x}^{(k)}\|_2^2.$$

The result follows because  $\vec{x}^{(k+1)} - \vec{x}^{(k)} = -\alpha_k \nabla f(\vec{x}^{(k)})$ .

## Question

- ▶ So How Should be Choose Learning Rate?

**Corollary** (Gradient descent is a descent method). *If  $\alpha_k \leq \frac{1}{L}$*

$$f(\vec{x}^{(k+1)}) \leq f(\vec{x}^{(k)}) - \frac{\alpha_k}{2} \|\nabla f(\vec{x}^{(k)})\|_2^2.$$

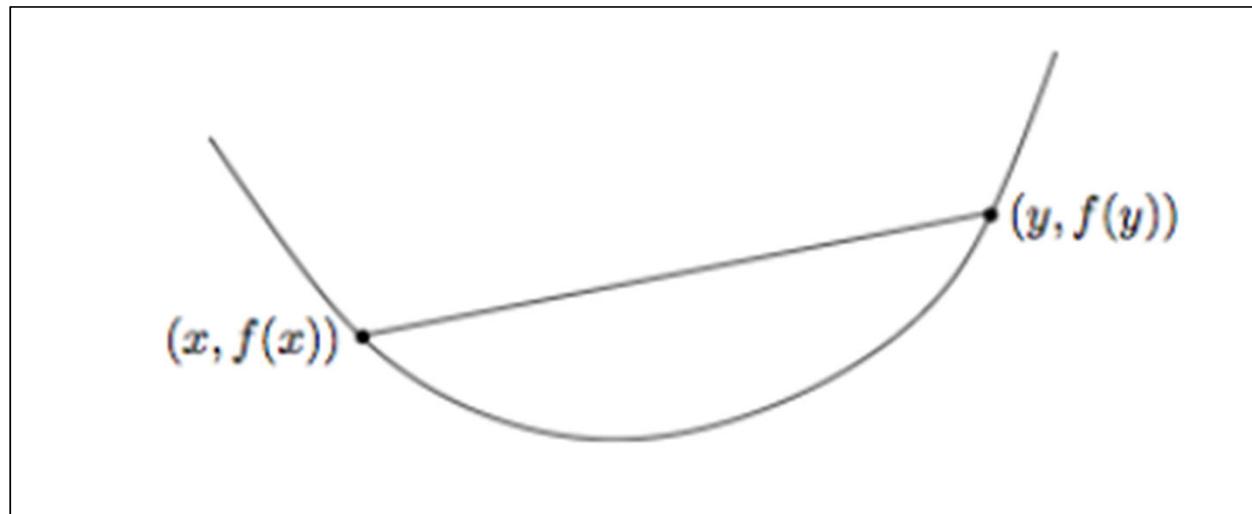

# Convergence Analysis

**Theorem :** We assume that  $f$  is convex,  $\nabla f$  is  $L$ -Lipschitz continuous and there exists a point  $\vec{x}^*$  at which  $f$  achieves a finite minimum. If we set the step size of gradient descent to  $\alpha_k = \alpha \leq 1/L$  for every iteration,

$$f(\vec{x}^{(k)}) - f(\vec{x}^*) \leq \frac{\|\vec{x}^{(0)} - \vec{x}^*\|_2^2}{2\alpha k}$$

# Convex Functions

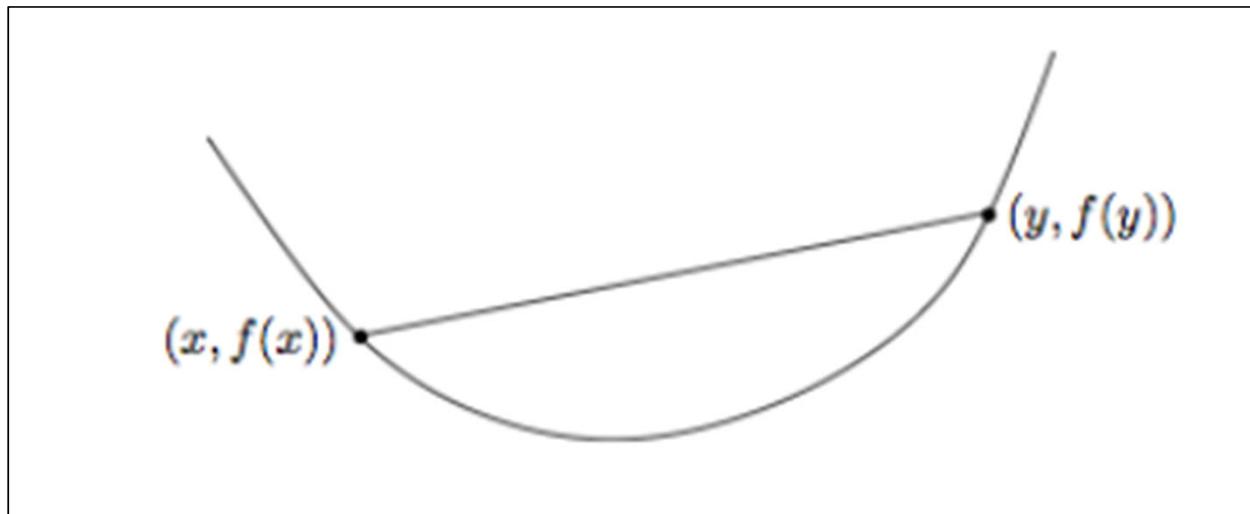

**Definition**  $f(\theta x + (1 - \theta)y) \leq \theta f(x) + (1 - \theta)f(y).$

**convex:** if there is a local minimum, then it is a **global** minimum

# Convex Functions

**Definition**  $f(\theta x + (1 - \theta)y) \leq \theta f(x) + (1 - \theta)f(y).$

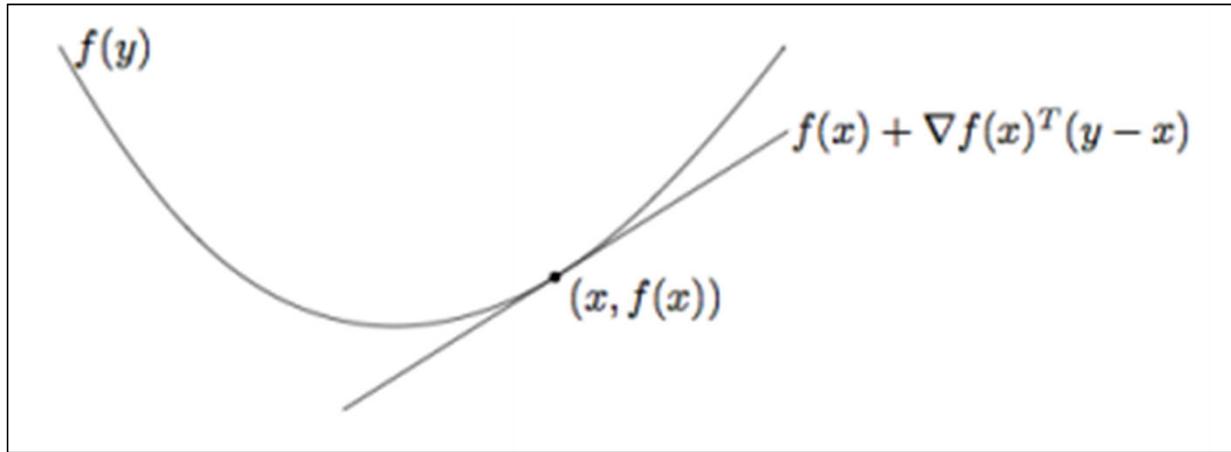

**convex:** if there is a local minimum, then it is a **global** minimum

## Convex Functions

$f$  is convex if and only if

$$f(y) \geq f(x) + \nabla f(x)^T(y - x)$$

# Convergence Analysis

**Theorem :** We assume that  $f$  is convex,  $\nabla f$  is  $L$ -Lipschitz continuous and there exists a point  $\vec{x}^*$  at which  $f$  achieves a finite minimum. If we set the step size of gradient descent to  $\alpha_k = \alpha \leq 1/L$  for every iteration,

$$f(\vec{x}^{(k)}) - f(\vec{x}^*) \leq \frac{\|\vec{x}^{(0)} - \vec{x}^*\|_2^2}{2\alpha k}$$

*Proof.* By the first-order characterization of convexity

$$f(\vec{x}^{(k-1)}) + \nabla f(\vec{x}^{(k-1)})^T (\vec{x}^* - \vec{x}^{(k-1)}) \leq f(\vec{x}^*),$$

# Convergence Analysis

*Proof.* By the first-order characterization of convexity

$$f(\vec{x}^{(k-1)}) + \nabla f(\vec{x}^{(k-1)})^T (\vec{x}^* - \vec{x}^{(k-1)}) \leq f(\vec{x}^*),$$

Gradient descent is a descent method

$$f(\vec{x}^{(k+1)}) \leq f(\vec{x}^{(k)}) - \frac{\alpha_k}{2} \|\nabla f(\vec{x}^{(k)})\|_2^2.$$

$$\begin{aligned} f(\vec{x}^{(k)}) - f(\vec{x}^*) &\leq \nabla f(\vec{x}^{(k-1)})^T (\vec{x}^{(k-1)} - \vec{x}^*) - \frac{\alpha}{2} \|\nabla f(\vec{x}^{(k-1)})\|_2^2 \\ &= \frac{1}{2\alpha} \left( \|\vec{x}^{(k-1)} - \vec{x}^*\|_2^2 - \|\vec{x}^{(k-1)} - \vec{x}^* - \alpha \nabla f(\vec{x}^{(k-1)})\|_2^2 \right) \\ &= \frac{1}{2\alpha} \left( \|\vec{x}^{(k-1)} - \vec{x}^*\|_2^2 - \|\vec{x}^{(k)} - \vec{x}^*\|_2^2 \right) \end{aligned}$$

# Convergence Analysis

**Theorem :** We assume that  $f$  is convex,  $\nabla f$  is  $L$ -Lipschitz continuous and there exists a point  $\vec{x}^*$  at which  $f$  achieves a finite minimum. If we set the step size of gradient descent to  $\alpha_k = \alpha \leq 1/L$  for every iteration,

$$f(\vec{x}^{(k)}) - f(\vec{x}^*) \leq \frac{\|\vec{x}^{(0)} - \vec{x}^*\|_2^2}{2\alpha k}$$

*Proof.*

$$\begin{aligned} f(\vec{x}^{(k)}) - f(\vec{x}^*) &\leq \frac{1}{k} \sum_{i=1}^k f(\vec{x}^{(k)}) - f(\vec{x}^*) \\ &\leq \frac{1}{2\alpha k} \left( \|\vec{x}^{(0)} - \vec{x}^*\|_2^2 - \|\vec{x}^{(k)} - \vec{x}^*\|_2^2 \right) \\ &\leq \frac{\|\vec{x}^{(0)} - \vec{x}^*\|_2^2}{2\alpha k}. \end{aligned}$$

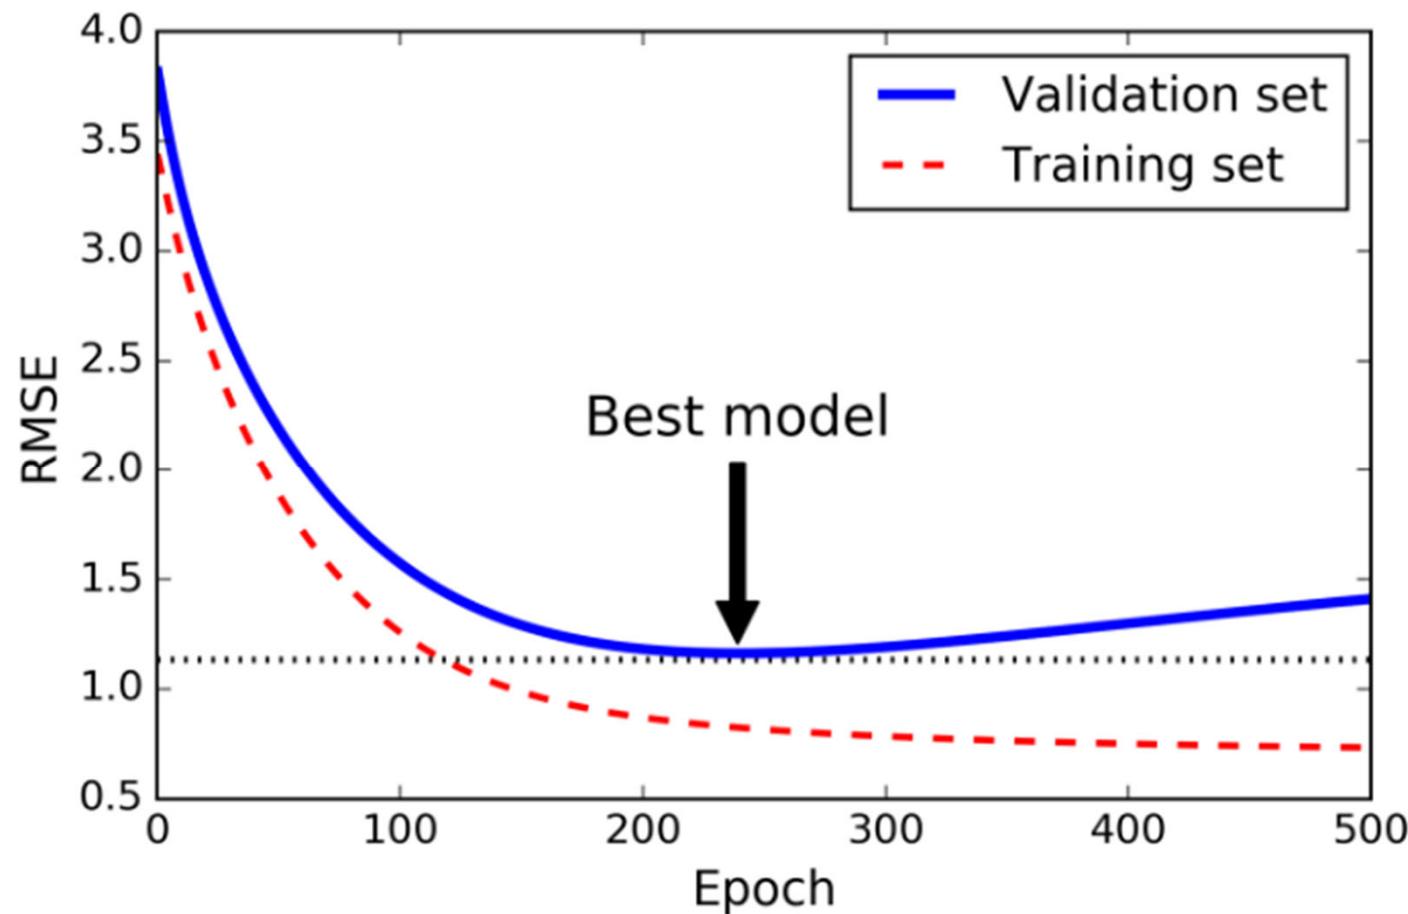

# Agenda

- ▶ Lesson
  - ▶ Properties Ridge
  - ▶ Properties of Lasso
  - ▶ Relationship between Ridge and Lasso
  - ▶ Line Search

## Objectives

- ▶ Why L2 shrink weights?
- ▶ Why L1 gives sparsity?
- ▶ What happens with repeated or correlated features.
- ▶ Explain line search algorithm

## Early Stopping

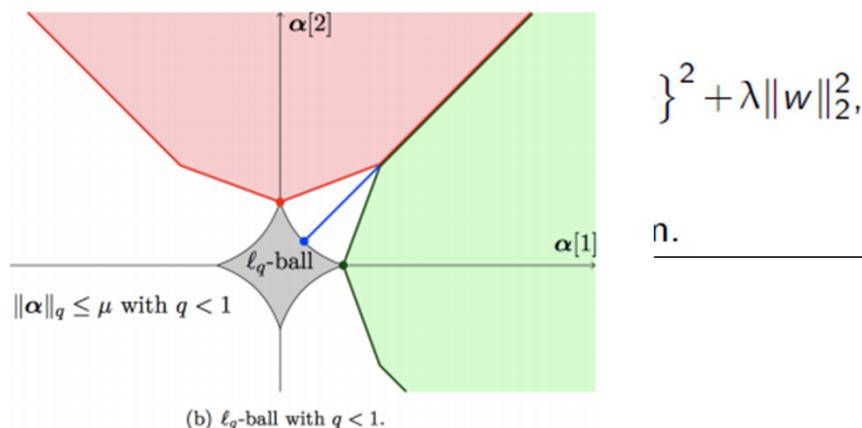

# Ridge Regression (Penalization and Constraint Forms)

## Ridge Regression (Tikhonov Form)

The ridge regression solution for complexity parameter  $\lambda \geq 0$  is

where  $\|w\|$

$$\}^2 + \lambda \|w\|_2^2,$$

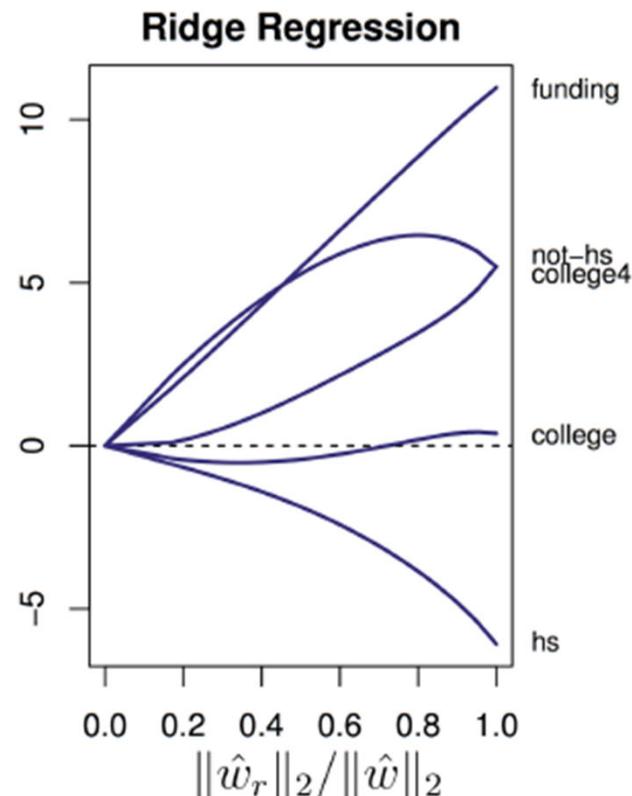

n.

## Ridge Regression (Ivanov Form)

The ridge regression solution for complexity parameter  $r \geq 0$  is

$$\hat{w} = \arg \min_{\|w\|_2^2 \leq r^2} \frac{1}{n} \sum_{i=1}^n \{ w^T x_i - y_i \}^2.$$

# Regularization Path of Ridge Regression

$$\hat{w}_r = \arg \min_{\|w\|_2^2 \leq r^2} \frac{1}{n} \sum_{i=1}^n (w^T x_i - y_i)^2$$
$$\hat{w} = \hat{w}_\infty = \text{Unconstrained ERM}$$

- For  $r = 0$ ,  $\|\hat{w}_r\|_2/\|\hat{w}\|_2 = 0$ .
- For  $r = \infty$ ,  $\|\hat{w}_r\|_2/\|\hat{w}\|_2 = 1$

## Ridge Regression and Stability

$$\hat{f}(x) = \hat{w}^T x,$$

$$\begin{aligned} |\hat{f}(x+h) - \hat{f}(x)| &= |\hat{w}^T (x+h) - \hat{w}^T x| = |\hat{w}^T h| \\ &\leq \|\hat{w}\|_2 \|h\|_2 \end{aligned}$$

## Ridge Regression Shrinks Weights

$$\operatorname{argmin}_{w \in \mathbb{R}^m} \left( \frac{1}{2m} \sum_{i=1}^m (x_i w - y_i)^2 + \lambda w^2 \right).$$

Then, the optimal solution is

$$w = \frac{\langle \mathbf{x}, \mathbf{y} \rangle / m}{\|\mathbf{x}\|^2 / m + 2\lambda}.$$

## Ridge Regression and Line Search

- ▶ Why can't we just solve for the minimum in line search?
- ▶ Actually we can...sort of...it's the Levenberg-Marquardt algorithm
- ▶ While it's an iterative algorithm, the important step in the algorithm involves solving the normal equations.

## Ridge Regression and Line Search

- ▶ Why can't we just solve for the minimum in line search?
- ▶ Actually we can...sort of...it's the Levenberg-Marquardt algorithm
- ▶ While it's an iterative algorithm, the important step in the algorithm involves solving the normal equations.

$$f(x_i, \beta + \delta) \approx f(x_i, \beta) + \mathbf{J}_i \delta,$$

where

$$\mathbf{J}_i = \frac{\partial f(x_i, \beta)}{\partial \beta}$$

## Levenberg-Marquardt algorithm

$$S(\boldsymbol{\beta} + \boldsymbol{\delta}) \approx \sum_{i=1}^m [y_i - f(x_i, \boldsymbol{\beta}) - \mathbf{J}_i \boldsymbol{\delta}]^2,$$

$$\begin{aligned} S(\boldsymbol{\beta} + \boldsymbol{\delta}) &\approx \|\mathbf{y} - \mathbf{f}(\boldsymbol{\beta}) - \mathbf{J}\boldsymbol{\delta}\|^2 \\ &= [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta}) - \mathbf{J}\boldsymbol{\delta}]^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta}) - \mathbf{J}\boldsymbol{\delta}] \\ &= [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})] - [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]^T \mathbf{J}\boldsymbol{\delta} - (\mathbf{J}\boldsymbol{\delta})^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})] + \boldsymbol{\delta}^T \mathbf{J}^T \mathbf{J}\boldsymbol{\delta} \\ &= [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})] - 2[\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]^T \mathbf{J}\boldsymbol{\delta} + \boldsymbol{\delta}^T \mathbf{J}^T \mathbf{J}\boldsymbol{\delta}. \end{aligned}$$

$$\boxed{(\mathbf{J}^T \mathbf{J}) \boldsymbol{\delta} = \mathbf{J}^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})],}$$

## Levenberg-Marquardt algorithm

$$S(\boldsymbol{\beta} + \boldsymbol{\delta}) \approx \sum_{i=1}^m [y_i - f(x_i, \boldsymbol{\beta}) - \mathbf{J}_i \boldsymbol{\delta}]^2,$$

$$\begin{aligned} S(\boldsymbol{\beta} + \boldsymbol{\delta}) &\approx \|\mathbf{y} - \mathbf{f}(\boldsymbol{\beta}) - \mathbf{J}\boldsymbol{\delta}\|^2 \\ &= [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta}) - \mathbf{J}\boldsymbol{\delta}]^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta}) - \mathbf{J}\boldsymbol{\delta}] \\ &= [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})] - [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]^T \mathbf{J}\boldsymbol{\delta} - (\mathbf{J}\boldsymbol{\delta})^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})] + \boldsymbol{\delta}^T \mathbf{J}^T \mathbf{J}\boldsymbol{\delta} \\ &= [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})] - 2[\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]^T \mathbf{J}\boldsymbol{\delta} + \boldsymbol{\delta}^T \mathbf{J}^T \mathbf{J}\boldsymbol{\delta}. \end{aligned}$$

$$(\mathbf{J}^T \mathbf{J} + \lambda \mathbf{I}) \boldsymbol{\delta} = \mathbf{J}^T [\mathbf{y} - \mathbf{f}(\boldsymbol{\beta})]$$

# Lasso Regression (Constraint and Penalization Forms)

## Lasso Regression (Tikhonov Form)

The lasso regression solution for regularization parameter  $\lambda \geq 0$  is

$$\hat{w} = \arg \min_{w \in \mathbb{R}^d} \frac{1}{n} \sum_{i=1}^n \{w^T x_i - y_i\}^2 + \lambda \|w\|_1,$$

where  $\|w\|_1 = |w_1| + \dots + |w_d|$  is the  $\ell_1$ -norm.

---

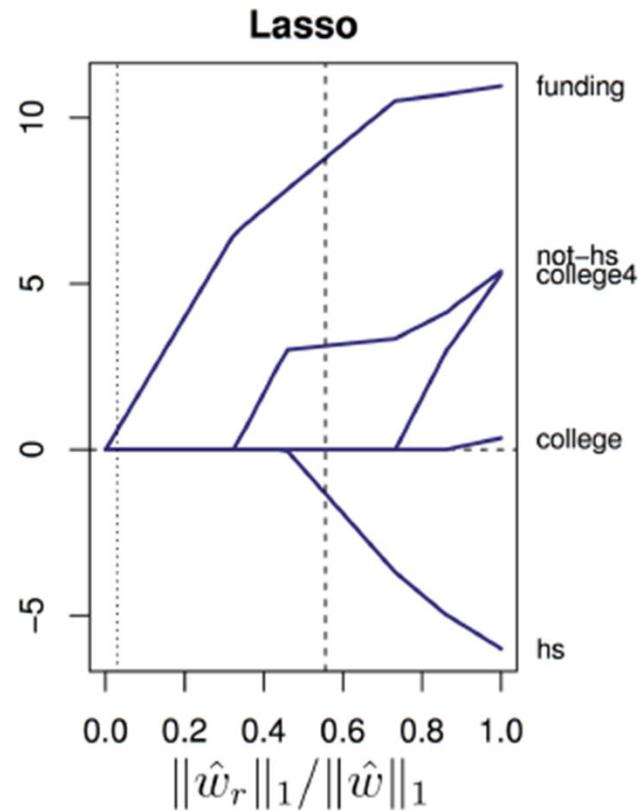

## Lasso Regression (Ivanov Form)

The lasso regression solution for complexity parameter  $r \geq 0$  is

$$\hat{w} = \arg \min_{\|w\|_1 \leq r} \frac{1}{n} \sum_{i=1}^n \{w^T x_i - y_i\}^2.$$

# Regularization Path of Lasso Regression

$$\hat{w}_r = \arg \min_{\|w\|_1 \leq r} \frac{1}{n} \sum_{i=1}^n (w^T x_i - y_i)^2$$
$$\hat{w} = \hat{w}_\infty = \text{Unconstrained ERM}$$

- For  $r = 0$ ,  $\|\hat{w}_r\|_1 / \|\hat{w}\|_1 = 0$ .
- For  $r = \infty$ ,  $\|\hat{w}_r\|_1 / \|\hat{w}\|_1 = 1$

## Lasso Regression Gives Sparsity

$$\min_{w \in \mathbb{R}} \left( \frac{1}{2} w^2 - xw + \lambda |w| \right).$$

solution to this problem is the “soft thresholding” operator

$$w = \text{sign}(x) [|x| - \lambda]_+,$$

where  $[a]_+ \stackrel{\text{def}}{=} \max\{a, 0\}$ .

# Lasso Regression Gives Sparsity

$$\operatorname{argmin}_{w \in \mathbb{R}^m} \left( \frac{1}{2m} \sum_{i=1}^m (x_i w - y_i)^2 + \lambda |w| \right).$$

We can rewrite the problem as

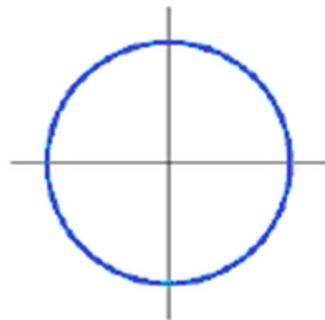

$$\operatorname{argmin}_{w \in \mathbb{R}^m} \left( \frac{1}{2} \left( \frac{1}{m} \sum_i x_i^2 \right) w^2 - \left( \frac{1}{m} \sum_{i=1}^m x_i y_i \right) w + \lambda |w| \right).$$

For simplicity let us assume that  $\frac{1}{m} \sum_i x_i^2 = 1$ , and denote  $\langle \mathbf{x}, \mathbf{y} \rangle = \sum_{i=1}^m x_i y_i$ ; then the optimal solution is

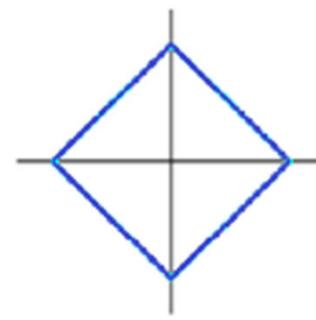

$$w = \operatorname{sign}(\langle \mathbf{x}, \mathbf{y} \rangle) [|\langle \mathbf{x}, \mathbf{y} \rangle|/m - \lambda]_+.$$

# Lasso Regression Gives Sparsity

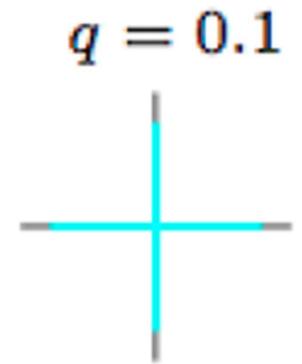

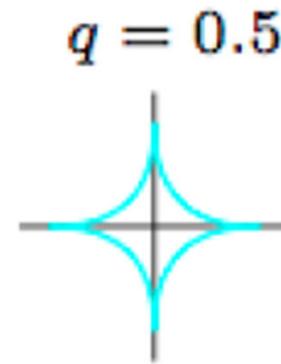

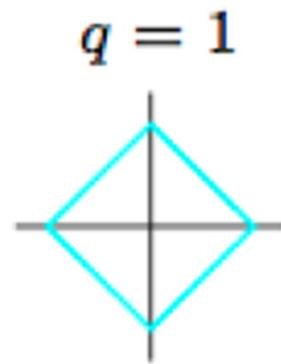

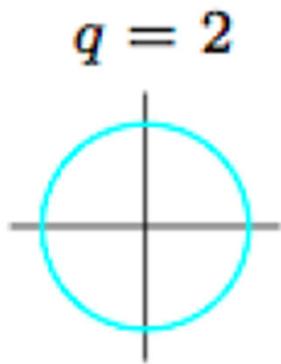

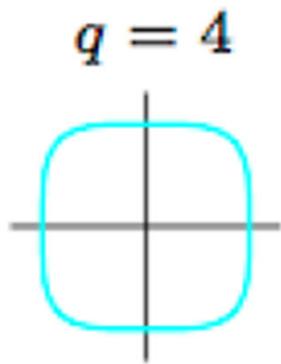

- $\ell_2$  contour:  
 $w_1^2 + w_2^2 = r$

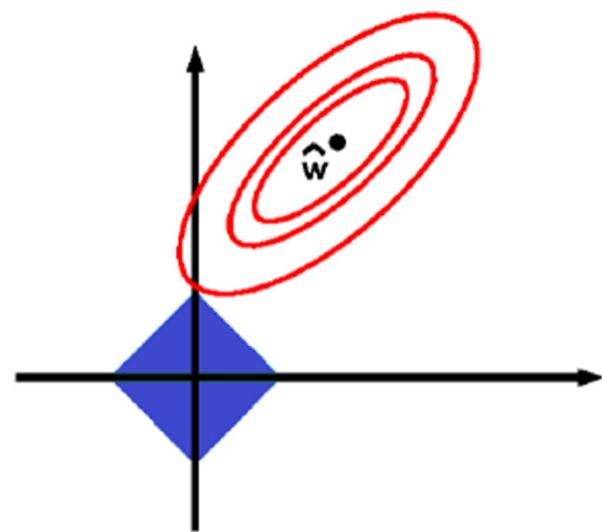

- $\ell_1$  contour:  
 $|w_1| + |w_2| = r$

## Lasso Regression Gives Sparsity

# Lasso Regression Gives Sparsity

- Blue region: Area satisfying complexity constraint:  $|w_1| + |w_2| \leq r$
- Red lines: contours of  $\hat{R}_n(w) = \sum_{i=1}^n (w^T x_i - y_i)^2$ .

# Lasso Regression Gives Sparsity

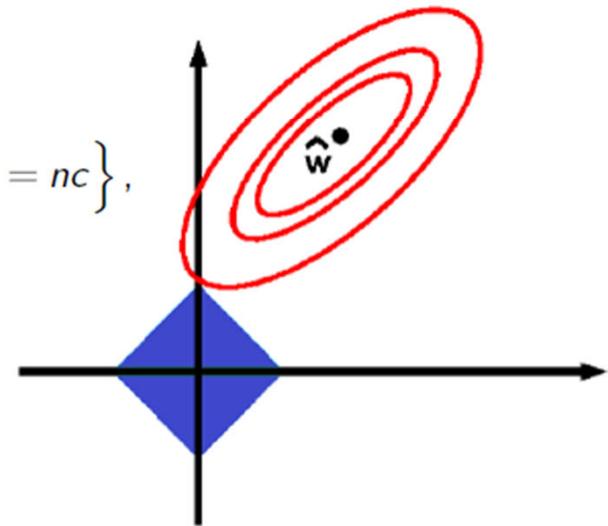

- By “completing the square”, we can show for any  $w \in \mathbb{R}^d$ :

$$\hat{R}_n(w) = \frac{1}{n} (w - \hat{w})^T X^T X (w - \hat{w}) + \hat{R}_n(\hat{w})$$

- Set of  $w$  with  $\hat{R}_n(w)$  exceeding  $\hat{R}_n(\hat{w})$  by  $c > 0$  is

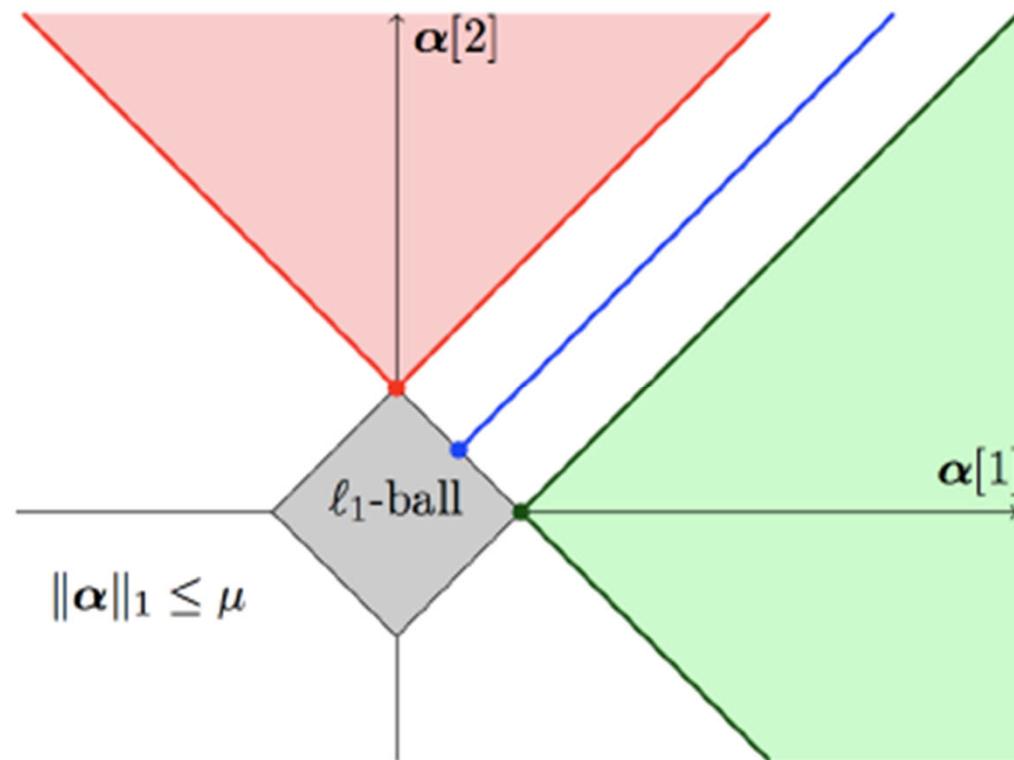

$$\left\{ w \mid \hat{R}_n(w) = c + \hat{R}_n(\hat{w}) \right\} = \left\{ w \mid (w - \hat{w})^T X^T X (w - \hat{w}) = nc \right\},$$

which is an **ellipsoid centered at  $\hat{w}$** .

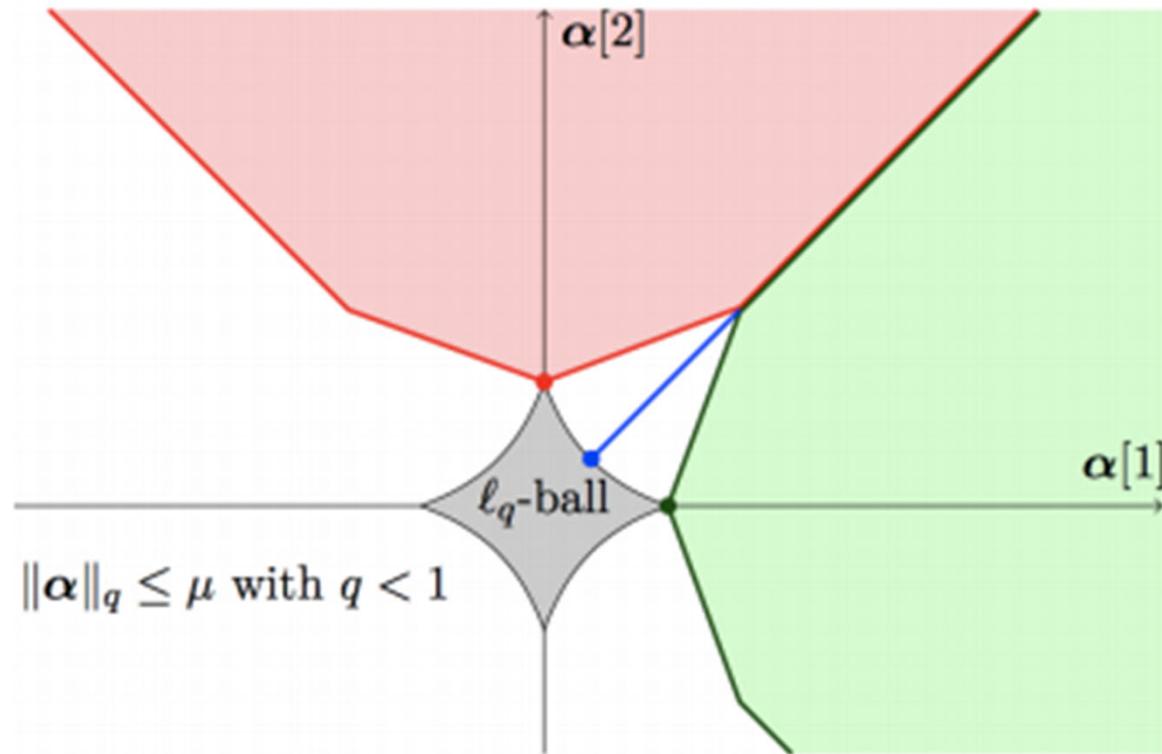

- Blue region: Area satisfying complexity constraint:  $|w_1| + |w_2| \leq r$
- Red lines: contours of  $\hat{R}_n(w) = \sum_{i=1}^n (w^T x_i - y_i)^2$ .

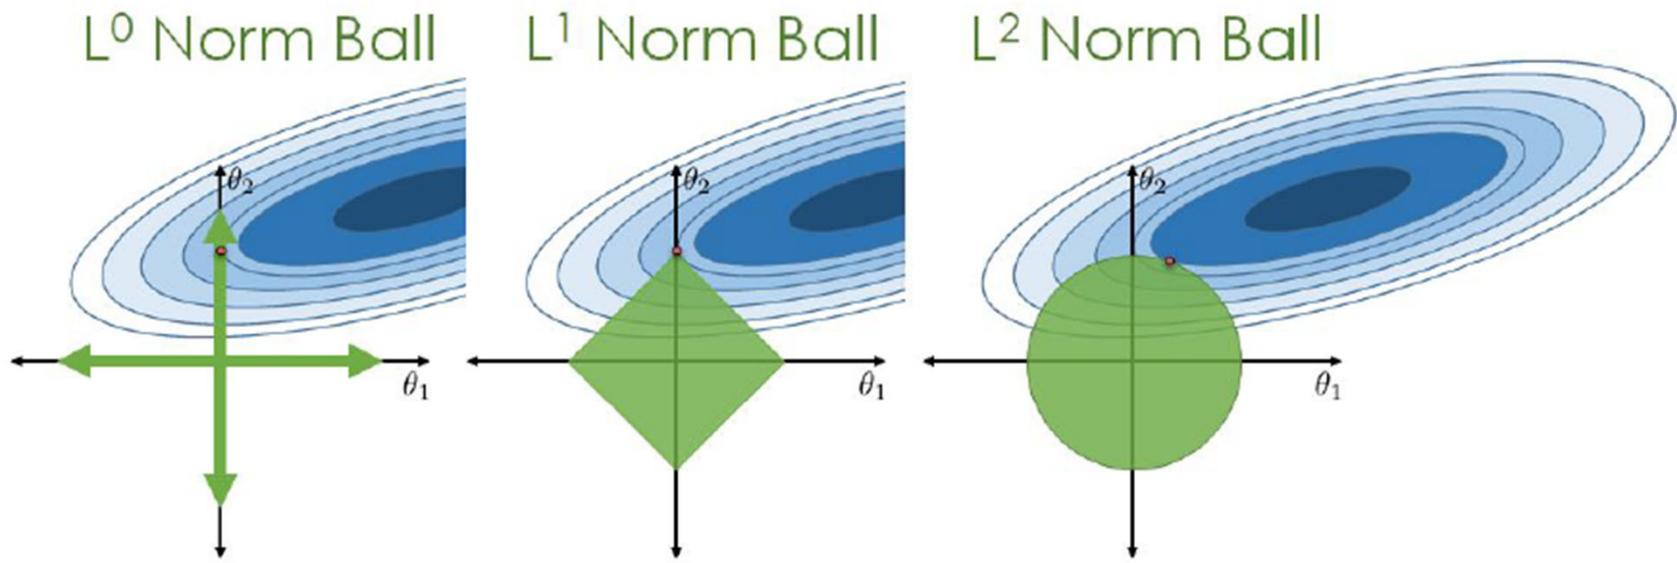

# Lasso Regression Gives Sparsity

# Lasso Regression Gives Sparsity

# Lasso Regression Gives Sparsity

**Ideal for  
Feature Selection**  
but combinatorically  
difficult to optimize

Encourages  
Sparse Solutions  
**Convex!**

Spreads weight  
over features (**robust**)  
does not  
encourage sparsity

## Lasso Regression Gives Sparsity

- ▶ Coefficient are 0 => don't need those features.  
What's the gain?
  - ▶ Time/expense to compute/buy features
  - ▶ Memory to store features (e.g. real-time deployment)
  - ▶ Identifies the important features
  - ▶ Better prediction? sometimes
  - ▶ As a feature-selection step for training a slower non-linear model

## Question

- ▶ Explain why feature normalization is important if you are using L1 or L2 regularization.
- ▶ Scaling
  - ▶ Centering and Scaling
  - ▶ Clipping
  - ▶ Min-Max
  - ▶ Transformation (Log, Sigmoid,...)

## How to work with absolute value?

- How to solve the Lasso?

$$\min_{w \in \mathbb{R}^d} \sum_{i=1}^n (w^T x_i - y_i)^2 + \lambda \|w\|_1$$

- $\|w\|_1 = |w_1| + |w_2|$  is not differentiable!

## How to work with absolute value?

- Consider any number  $a \in \mathbb{R}$ .
- Let the **positive part** of  $a$  be

$$a^+ = a1(a \geq 0).$$

- Let the **negative part** of  $a$  be

$$a^- = -a1(a \leq 0).$$

- Do you see why  $a^+ \geq 0$  and  $a^- \geq 0$ ?
- How do you write  $a$  in terms of  $a^+$  and  $a^-$ ?
- How do you write  $|a|$  in terms of  $a^+$  and  $a^-$ ?

## How to work with absolute value?

- The Lasso problem

$$\min_{w \in \mathbb{R}^d} \sum_{i=1}^n (w^T x_i - y_i)^2 + \lambda \|w\|_1$$

- Replace each  $w_i$  by  $w_i^+ - w_i^-$ .
- Write  $w^+ = (w_1^+, \dots, w_d^+)$  and  $w^- = (w_1^-, \dots, w_d^-)$ .

## How to work with absolute value?

We will show: substituting  $w = w^+ - w^-$  and  $|w| = w^+ + w^-$  gives an equivalent problem:

$$\begin{aligned} \min_{w^+, w^-} \quad & \sum_{i=1}^n \left( (w^+ - w^-)^T x_i - y_i \right)^2 + \lambda \mathbf{1}^T (w^+ + w^-) \\ \text{subject to} \quad & w_i^+ \geq 0 \text{ for all } i \quad w_i^- \geq 0 \text{ for all } i, \end{aligned}$$

- Objective is **differentiable** (in fact, **convex and quadratic**)
- $2d$  variables vs  $d$  variables and  $2d$  constraints vs no constraints

## How to work with absolute value?

Lasso problem is trivially equivalent to the following:

$$\begin{aligned} \min_w \min_{a,b} \quad & \sum_{i=1}^n \left( (a-b)^T x_i - y_i \right)^2 + \lambda \mathbf{1}^T (a+b) \\ \text{subject to} \quad & a_i \geq 0 \text{ for all } i \quad b_i \geq 0 \text{ for all } i, \\ & a - b = w \\ & a + b = |w| \end{aligned}$$

- Claim: Don't need constraint  $a+b=|w|$ .
- $a' \leftarrow a - \min(a, b)$  and  $b' \leftarrow b - \min(a, b)$  at least as good
- So if  $a$  and  $b$  are minimizers, at least one is 0.
- Since  $a-b=w$ , we must have  $a=w^+$  and  $b=w^-$ . So also  $a+b=|w|$ .

## How to work with absolute value?

- So lasso optimization problem is equivalent to

$$\min_{a,b} \quad \sum_{i=1}^n \left( (a-b)^T x_i - y_i \right)^2 + \lambda \mathbf{1}^T (a+b)$$

subject to  $a_i \geq 0$  for all  $i$        $b_i \geq 0$  for all  $i$ ,

where at the end we take  $w^* = a^* - b^*$  (and we've shown above that  $a^*$  and  $b^*$  are positive and negative parts of  $w^*$ , respectively.)

- Has constraints – how do we optimize?

# Projected (Stochastic) Gradient Descent

$$\begin{aligned} & \min_{w^+, w^- \in \mathbb{R}^d} \sum_{i=1}^n \left( (w^+ - w^-)^T x_i - y_i \right)^2 + \lambda \mathbf{1}^T (w^+ + w^-) \\ & \text{subject to } w_i^+ \geq 0 \text{ for all } i \\ & \quad w_i^- \geq 0 \text{ for all } i \end{aligned}$$

- Just like SGD, but after each step
  - Project  $w^+$  and  $w^-$  into the constraint set.
  - In other words, if any component of  $w^+$  or  $w^-$  becomes negative, set it back to 0.

# Lasso Regression and Line Search

- **Goal:** Minimize  $L(w) = L(w_1, \dots, w_d)$  over  $w = (w_1, \dots, w_d) \in \mathbf{R}^d$ .
- In gradient descent or SGD,
  - each step potentially changes all entries of  $w$ .
- In each step of **coordinate descent**,
  - we adjust only a single  $w_i$ .
- In each step, solve

$$w_i^{\text{new}} = \arg \min_{w_i} L(w_1, \dots, w_{i-1}, \mathbf{w}_i, w_{i+1}, \dots, w_d)$$

- Solving this argmin may itself be an iterative process.
- Coordinate descent is great when
  - it's easy or easier to minimize w.r.t. one coordinate at a time

# Shooting Algorithm

$$\hat{w}_j = \arg \min_{w_j \in \mathbb{R}} \sum_{i=1}^n (w^T x_i - y_i)^2 + \lambda |w|_1$$

Then

$$\hat{w}_j = \begin{cases} (c_j + \lambda)/a_j & \text{if } c_j < -\lambda \\ 0 & \text{if } c_j \in [-\lambda, \lambda] \\ (c_j - \lambda)/a_j & \text{if } c_j > \lambda \end{cases}$$

$$a_j = 2 \sum_{i=1}^n x_{i,j}^2 \quad c_j = 2 \sum_{i=1}^n x_{i,j} (y_i - w_{-j}^T x_{i,-j})$$

where  $w_{-j}$  is  $w$  without component  $j$  and similarly for  $x_{i,-j}$ .

# Shooting Algorithm

- ▶ Lasso
  - ▶ Explain what coordinate descent is, and why it is of particular interest for the Lasso.
  - ▶ Lasso optimization problem does not have a differentiable objective function. Give an equivalent formulation that has a differentiable objective function by dividing the weight vector into positive and negative parts.
  - ▶ Give reasons why we might want the sparsity that L1 regularization often provides.

## Lasso Regression and Stability

- Suppose we have one feature  $x_1 \in \mathbf{R}$ .
- Response variable  $y \in \mathbf{R}$ .
- Got some data and ran least squares linear regression.
- The ERM is

$$\hat{f}(x_1) = 4x_1.$$

- What happens if we get a new feature  $x_2$ ,
  - but we always have  $x_2 = x_1$ ?

## Lasso Regression and Stability

- New feature  $x_2$  gives no new information.
- ERM is still

$$\hat{f}(x_1, x_2) = 4x_1.$$

- Now there are some more ERMs:

$$\hat{f}(x_1, x_2) = 2x_1 + 2x_2$$

$$\hat{f}(x_1, x_2) = x_1 + 3x_2$$

$$\hat{f}(x_1, x_2) = 4x_2$$

- What if we introduce  $\ell_1$  or  $\ell_2$  regularization?

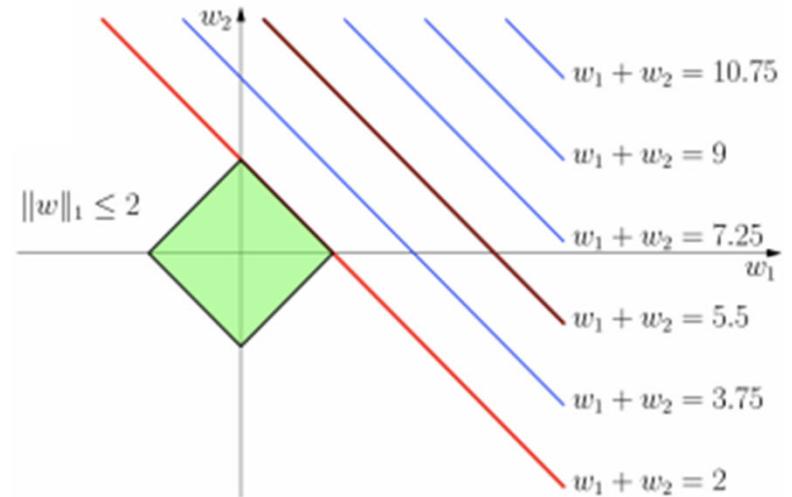

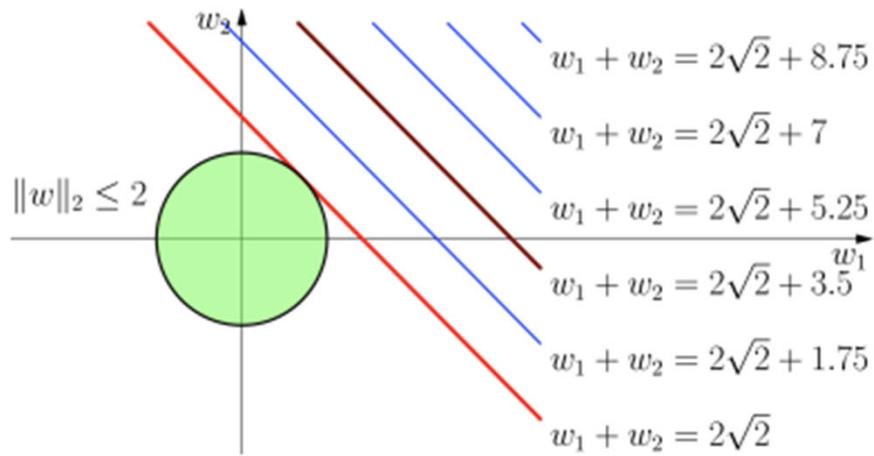

## Lasso Regression and Stability

- $\hat{f}(x_1, x_2) = w_1 x_1 + w_2 x_2$  is an ERM iff  $w_1 + w_2 = 4$ .
- Consider the  $\ell_1$  and  $\ell_2$  norms of various solutions:

$w_1$	$w_2$	$\ w\ _1$	$\ w\ _2^2$
4	0	4	16
2	2	4	8
1	3	4	10
-1	5	6	26

- $\|w\|_1$  doesn't discriminate, as long as all have same sign
- $\|w\|_2^2$  minimized when weight is spread equally
- Picture proof: Level sets of loss are lines of the form  $w_1 + w_2 = 4\dots$

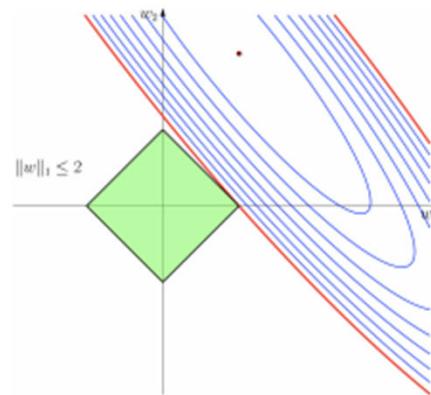

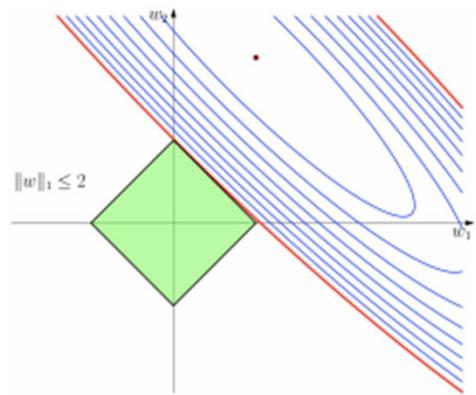

# Lasso Regression and Stability

## Lasso Regression and Stability

- Suppose  $x_1$  and  $x_2$  are highly correlated and the same scale.
- This is quite typical in real data, after normalizing data.
- Nothing degenerate here, so level sets are ellipsoids.
- But, the higher the correlation, the closer to degenerate we get.
- That is, ellipsoids keep stretching out, getting closer to two parallel lines.

# Lasso Regression and Stability

- Intersection could be anywhere on the top right edge.
- Minor perturbations (in data) can drastically change intersection point – very unstable solution.
- Makes division of weight among highly correlated features (of same scale) seem arbitrary.
  - If  $x_1 \approx 2x_2$ , ellipse changes orientation and we hit a corner. (Which one?)

# Lasso Regression and Stability

- Suppose there's some unknown value  $\theta \in \mathbf{R}$ .
- We get 3 noisy observations of  $\theta$ :

$$x_1, x_2, x_3 \sim \mathcal{N}(\theta, 1) \text{ (i.i.d)}$$

- What's a good estimator  $\hat{\theta}$  for  $\theta$ ?
- Would you prefer  $\hat{\theta} = x_1$  or  $\hat{\theta} = \frac{1}{3}(x_1 + x_2 + x_3)$ ?

## Lasso Regression and Stability

- $\mathbb{E}[x_1] = \theta$  and  $\mathbb{E}\left[\frac{1}{3}(x_1 + x_2 + x_3)\right] = \theta$ . So both unbiased.
- $\text{Var}[x_1] = 1$ .
- $\text{Var}\left[\frac{1}{3}(x_1 + x_2 + x_3)\right] = \frac{1}{9}(1+1+1) = \frac{1}{3}$ .
- Average has a smaller variance — the independent errors cancel each other out.
- Similar thing happens in regression with correlated features:
  - e.g. If 3 features are correlated, we could keep just one of them.
  - But we can potentially do better by using all 3.

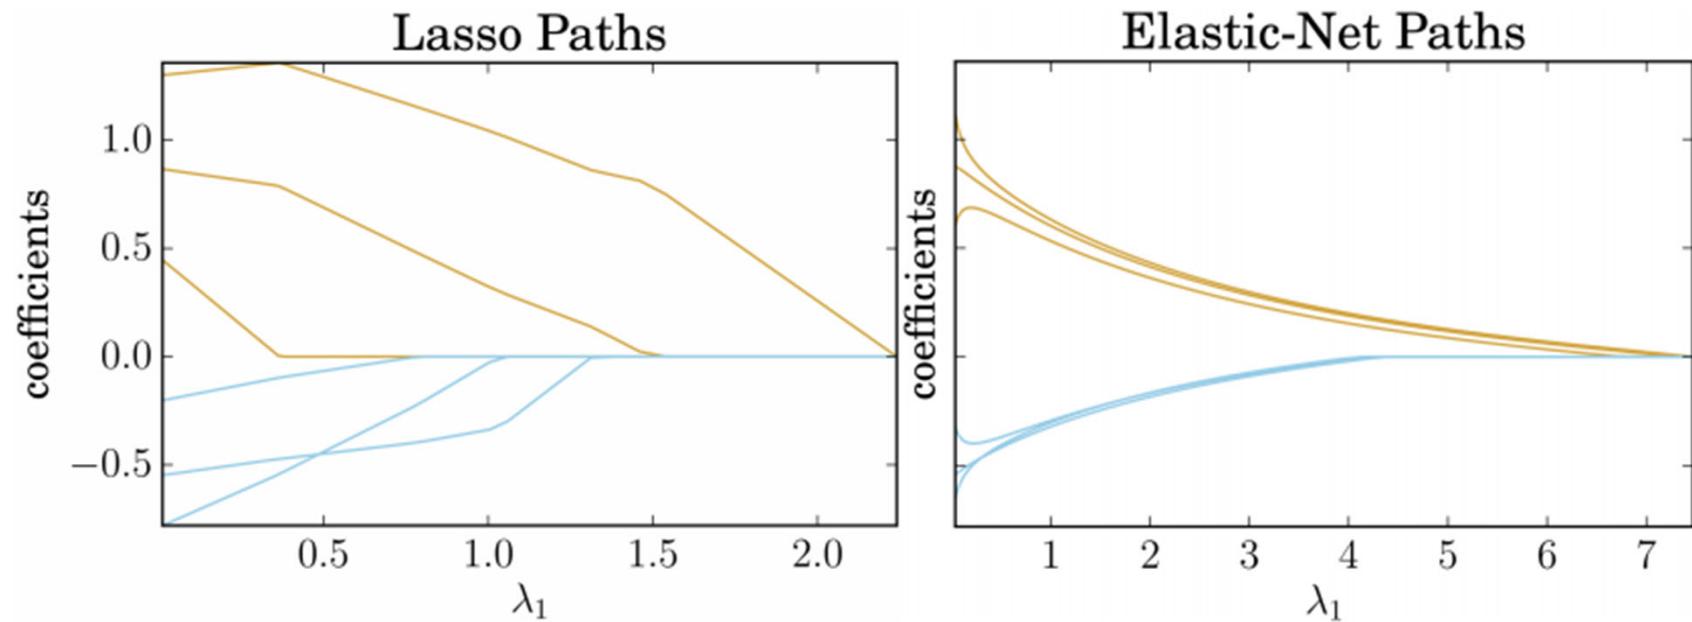

## Elastic Net

- The **elastic net** combines lasso and ridge penalties:

$$\hat{w} = \arg \min_{w \in \mathbb{R}^d} \frac{1}{n} \sum_{i=1}^n \{ w^T x_i - y_i \}^2 + \lambda_1 \|w\|_1 + \lambda_2 \|w\|_2^2$$

- We expect correlated random variables to have similar coefficients.

# Elastic Net

## Take-Aways

- ▶ Lasso
  - ▶ Explain what coordinate descent is, and why it is of particular interest for the Lasso.
  - ▶ Lasso optimization problem does not have a differentiable objective function. Give an equivalent formulation that has a differentiable objective function by dividing the weight vector into positive and negative parts.
  - ▶ Give reasons why we might want the sparsity that L1 regularization often provides.

## Take-Aways

- ▶ Ridge versus Lasso
  - ▶ Explain what happens when we do linear, lasso, and ridge regression with 2 identical features.
  - ▶ Explain what happens when  $x_1$  and  $x_2$  are highly correlated, but not exactly linearly related.
  - ▶ Why does Elastic Net provide us benefits of both L1 and L2 regularization?
